A simple programming exercise

Just going on scale.

1. Write a sorting program in any programming language that you are comfortable with.
 - The sorting action should be a callable function, callable from anywhere.
 - The main function or method should be independent of this sorting function.
 - Input to the sorting function at the time of call must be supplied by the caller.
 - If the input is not all in the main memory of the program, then the sorting function must have access to the functions or methods that read and supply the input as and when needed.
2. Once completed and tested, put this sorting program to test on various inputs.
 - On the usual keyboard input.
 - On input redirection from a file.
 - Input and output both from and to the same file.
 - Network stream input, and output on the screen.
