Last Year's Practice Assignment in Preparation for a Tutorial on Module Independence

Suppose there are two modules that use two declarations for the same named class:

The Class Module

```
class FullClass {
private :
    int objectId, *data, size;
public :
    FullClass(void);
    FullClass(int);
    FullClass(int, int*);
    FullClass(const FullClass&);
    void tell(void);
    void setNthElement(int,int);
    ~FullClass(void);
};
```

|| The User Module

```
class FullClass {
public :
    FullClass(void);
    FullClass(int);
    FullClass(int, int*);
    FullClass(const FullClass&);
    void tell(void);
    void setNthElement(int,int);
    ~FullClass(void);
};
```

All the member functions (methods) of the class are in the class module. The user module is developed *independently*, without regard to the implementation of the class module. (That's the purpose in all the information hiding, isn't it?)

You are to implement this, fleshing out the modules (function bodies), and testing them with a main application. You may need or want to refer to your submission while doing the assignment 17-24 Sept.
